## Editing began long ago

A person puts on glasses in the morning, checks an insulin pump, replaces the battery in a hearing aid and covers an old surgical scar with a tattoo. None of these actions feels like science fiction. Yet together they open an uncomfortably large question: where does the body we are "given" end, and where does the body begin that we continually shape through tools, medicine, technique, decoration and social expectation? [1]

We were editing the body long before chips and gene editing. Clothing, training, fasting, painting, scarification, orthodontics, surgery, medication and ritual all alter how the body functions or signifies. Modern technology did not invent modification from nothing. It can intervene more deeply, more durably and with greater resolution in what earlier practices changed mainly at the surface or for limited periods.

Continuity does not erase differences of kind. Removable glasses are not the same as an implanted electrode. An inheritable genetic intervention is not the same as either. A digital prosthesis that continuously sends data to a manufacturer creates another category again. "Body modification" is too broad to be useful unless depth, reversibility, purpose, risk and social setting are specified.

## Therapy or enhancement?

The boundary between therapy and enhancement is drawn through social negotiation; technology alone cannot decide it. Correcting short-sightedness is usually treated as therapy. What happens when the same device magnifies beyond ordinary vision, provides night sight or overlays continuous digital information? A hand prosthesis may restore grasping, but if it becomes stronger, more precise or modular, restoration and augmentation begin to share a vocabulary. [3][4][5][8]

"Normal functioning" is not a stable measure either. Age, culture, profession and environment affect what counts as expected capacity. Hearing technology can be described as treatment, while parts of Deaf culture understand deafness as identity and reject the assumption that every difference must be repaired. The decision therefore concerns more than what medical engineering can do. It also concerns who has the authority to name a condition as lack.

Enhancement can adapt the person to a harmful environment instead of changing the environment. If work routinely produces sleep deprivation, it may be easier to offer alertness-enhancing drugs than to redesign schedules. If a school rewards only one narrow attention profile, intervention arrives more quickly in the child's body than in the institution. Editability can become a convenient escape route for society: structural failure is translated into an individual biological task.

### Aid, identity and data gateway

A prosthesis can be assistance, identity, instrument and data gateway at once. It restores function, alters body image, shapes social responses and, when networked, may generate information about movement, condition and use. For the wearer it can become part of the body while remaining, in law, a product, software license or subscription service. [2]

This creates a peculiar conflict of ownership. Who controls a system built into the body: the user, clinician, manufacturer, insurer or platform without which updates fail? What happens when a company closes, servers are retired, prices rise or new terms must be accepted for a security patch? A pacemaker, insulin pump or neural interface cannot be treated like an ordinary phone application, yet digital dependencies are moving ever closer to vital function.

Data are not a harmless by-product. Information collected by bodily devices can be exceptionally sensitive because it does not merely record what people say about themselves. It may reveal how they move, sleep, respond or deteriorate. As the body becomes editable, it also becomes measurable. Freedom cannot therefore be assessed solely by asking whether a person initially chose the device. Access, alternatives, data governance and the possibility of exit determine the quality of that choice.

## Freedom becoming obligation

The freedom to modify can become an obligation to modify. While an enhancement is rare and expensive, it appears to be an individual option. Once common, employers, insurers, militaries, schools or competitive markets may turn it into a new baseline. Those who refuse remain formally free but may be disadvantaged in practice. [10]

Sport makes this dynamic visible. If a performance intervention works, regulation concerns more than individual risk. It concerns whether others must accept the same intervention to remain competitive. The principle that "everyone decides for themselves" breaks where one person's choice rewrites the minimum conditions of entry for everyone else.

A similar tension appears with cognitive enhancement. If a device genuinely improves attention or memory, use may begin as advantage and become expectation. No explicit command is required. Selection systems need only reward users consistently. Coercion then arrives as a statistical disadvantage attached to refusal, without requiring a formal law.

## Inequality embedded in the body

Unequal access can turn bodily technology into a social layer. Better implants, more accurate diagnosis, personalized gene therapy or advanced prostheses may affect employability, longevity, learning and status. If such technologies remain available only to narrow groups, social inequality can acquire biological and technical form. [5]

This does not mean every enhancement necessarily increases inequality. Mass production and public provision can lower cost, and inexpensive assistive technology can open opportunities to people previously excluded. Effects depend on ownership, finance and regulation. The same technology may operate as public service, luxury good or employer surveillance device.

A sharp division between "natural" and "enhanced" humans is therefore premature. A more plausible future consists of many partially modified states, with different levels of access and dependency. Two species do not face one another. A complex social gradient emerges along which devices, abilities and updates gradually become normal.

## Religion, body and human measure

Religious concern is not a single prohibition. The sanctity of the body, the duty to heal and the question of human measure may point in different directions. Many traditions preserve both respect for the given body and an obligation to relieve suffering. An intervention is not accepted or rejected merely because it is artificial. Purpose, proportionality, dignity, communal consequences and the distinction between healing, replacement and norm enforcement matter.

Religious interpretations of the body are not always framed as individual ownership. The body may be gift, responsibility, relation or site of spiritual practice. Different questions follow from this than from the modern formula "my body, my choice". Autonomy remains important, but communal ethics also asks what relations a decision creates and what image of the human it turns into a norm.

Technological optimism and religious caution need not be absolute opposites. Medical history contains many tools once considered unnatural and later integrated into ordinary care. Debate becomes

productive when labels are replaced by a specific intervention: what does it change, at what cost, by whose decision and with what reversibility?

## A disability perspective

Futures of enhancement often speak of disability as a technical deficit waiting to be corrected. Disability studies offer a more layered account. Limitation arises partly from bodily condition and partly from environmental design. A staircase creates a barrier; a ramp or lift changes the possibilities of the same body. [6][7]

This view does not deny the value of treatment or technical support. It warns against tying dignity to repairability. If society accepts only bodies that approach a narrow standard, enhancement can become eugenic pressure. Technology then does not free difference. It hides the community's failure to accommodate it.

User experience is a central source; treating it as supplementary evidence loses the decisive friction. Engineering performance does not reveal by itself how a prosthesis fits into a life, how tiring it is, how repairable, or what social reactions it produces. Bodily technology should be evaluated by those who carry it as well as by those who design it.

## Cyberpunk: the body as economic surface

Cyberpunk 2077 is powerful because it presents the modified body as an economic and political relation, extending well beyond spectacle. An implant may grant power while creating dependence on manufacturers, technicians, black markets, corporate law and maintenance. The body does not simply become stronger. It enters a supply chain. [9]

In the game's world, modification is tied to status and survival. Those who do not upgrade may fall behind; those who upgrade excessively may lose bodily and psychological stability; those with corporate backing gain access to better systems. This is fiction, deliberately intensified. Its value lies less in predictive accuracy than in compressing access, identity, dependency and human limits into one urban environment.

Cyberpunk repeatedly asks how much modification a person can undergo and remain the same. The dramatic question is strong, but philosophically the percentage may not be decisive. Identity involves memory, relation, body, narrative and legal continuity. An implant does not automatically erase it, although interventions that alter perception, decision or memory can transform important parts of the self. The boundary cannot be assigned to one component.

## Consent and reversibility

Consent is robust only when a person understands risk, has a real alternative and is not deciding under a dependency that makes refusal impossible. Bodily technologies add a temporal dimension. An intervention may be acceptable now and burdensome ten years later under a different manufacturer, standard or life situation. Long-term maintenance and exit conditions are therefore part of the original ethical quality of the choice.

Reversibility extends beyond medicine. A device may be physically removable while its data, social expectations or labor-market effects remain. The reverse is also true: a permanent intervention may be ethically acceptable when need is clear, risk proportionate and the person's decision stable.

Children and future generations present the hardest cases. Parents routinely make irreversible choices, but inheritable modifications affect people who could not participate in consent. Autonomy, care, risk and justice enter the same decision space.

## An FD reading: the boundary opens into a decision field

The central question of bodily editing opens in four directions: who decides, who pays, who bears failure and whether return is possible. FD can help keep technological possibility separate from ethical permission, individual benefit from social effect, therapy from norm enforcement, and present performance from the full lifecycle of a device.

An intervention may be medically beneficial, dangerous in data governance and unequal in access at the same time. It may be individually voluntary while producing collective pressure. It may be religiously contested yet accepted because it relieves suffering. Multi-valued assessment is not an error of uncertainty here. It reflects the object itself.

A stable decision requires at least five layers: purpose and expected benefit; bodily and psychological risk; autonomy and consent; access and social consequences; ownership, data and long-term responsibility. When one layer is absent, technological enthusiasm tends to replace it with an attractive but weak story.

## The body as a constrained canvas

The body is editable, but not without limit or consequence. It is not a blank canvas because it has history, material, vulnerability and social meaning. Nor is it a sealed sanctuary that must never be touched. Much of human life consists of caring for, repairing, decorating and reinterpreting what we have received.

The coming decades are unlikely to deliver one dramatic "posthuman moment". They will bring many

smaller decisions: better prostheses, smarter implants, more precise gene therapies, tighter data connections and new expectations at work. Change will arrive less often with trumpets than with an update notification.

That is why the technological question requires a stronger culture of decision. Such a language leaves possibility open while refusing to call every buildable intervention progress. The future of the body combines engineering with a personal, social and political agreement about what counts as help, what price is acceptable, and who remains fully human even when they refuse the update.
